## Summary

In recent years, there has been a major boom in the development of multimodal machine learning models. Among open topics, representation (fusion) and generation of multimodal data are very active fields of research. Recently, Multimodal Variational Autoencoders (VAEs) have been attracting growing interest for both tasks, thanks to their versatility, scalability, and interpretability as probabilistic latent variable models. They are also particularly interesting models in the *partially observed* setting, as most of them can be trained even with missing data. This last point makes them particularly interesting for the medical field, where missing data are commonplace ([Antelmi et al., 2019](#); [Lawry Aguila et al., 2023](#)).

We present MultiVae, an open-source Python library for bringing together unified implementations of multimodal VAEs. It has been designed for easy, customizable use of these models on fully or partially observed data. This library also facilitates the development and benchmarking of new algorithms by integrating several benchmark datasets, a variety of evaluation metrics and tools for monitoring and sharing models.

## Multimodal Variational Autoencoders

In Multimodal Machine Learning, two goals are generally targeted: (1) Learn a shared representation from multiple modalities; (2) Learn to generate one missing modality given the ones that are available.

Multimodal Variational Autoencoders aim at solving both issues at the same time. These models learn a latent representation  $z$  of all modalities in a lower dimensional common space and learn to *decode*  $z$  to generate any modality.

Let  $X = (x_1, x_2, \dots, x_M)$  contain  $M$  modalities. In the VAE setting, we suppose that the generative process behind the observed data is the following:

$$z \sim p(z) \quad \text{and} \quad \forall 1 \leq i \leq M, x_i | z \sim p_\theta(x_i | z), \quad (1)$$

where  $p(z)$  is a prior distribution that is often fixed, and  $p_\theta(x_i | z)$  are called *decoders* and are parameterized by neural network. Typically,  $p_\theta(x_i | z) = \mathcal{N}(x_i; \mu_\theta(z), \sigma_\theta(z))$  where  $\mu_\theta, \sigma_\theta$  are neural networks. We aim to learn these *decoders* that translate  $z$  into the high dimensional data  $x_i$ . At the same time, we aim to learn an *encoder*  $q_\phi(z | X)$  that map observations to the latent space.  $q_\phi(z | X)$  is also parameterized by a neural network. Derived from variational inference ([Kingma & Welling, 2014](#)), the VAE objective writes:

$$\mathcal{L}(X) = \mathbb{E}_{q_\phi(z | X)} \left( \sum_i \ln(p_\theta(x_i | z)) \right) - KL(q_\phi(z | X) | p(z))$$

The first term is a reconstruction loss and the second term can be seen as a regularization term that avoids overfitting. A typical training step of a multimodal VAE consists in encoding the data with the encoder, reconstructing each modality with the decoders and taking a gradient step to optimize the loss  $\mathcal{L}(X)$ .

Most multimodal VAEs differ in how they construct the encoder  $q_\phi(z|X)$ . In the figure below, we summarize several approaches: *Aggregated models* (Shi et al., 2019; Sutter et al., 2021; Wu & Goodman, 2018) use a mean or a product operation to aggregate the information coming from all modalities, where *Joint models* (Senellart et al., 2023; Suzuki et al., 2016; Vedantam et al., 2018) use a neural network taking all modalities as input. Finally *coordinated models* (Tian & Engel, 2019; Wang et al., 2017a) use different latent spaces but add a constraint term in the loss to force them to be similar.

↔ : Similarity constraint

In our library, we implement all these approaches in an unified and modular way.

Aggregated models offer a natural way of learning on incomplete datasets: for an incomplete sample  $X$ , we use only the available modalities to encode the data and compute the loss that we minimize during training. However, except in our library MultiVae, there does not exist an implementation of these models that can be used on incomplete datasets in a straightforward manner.

## Data Augmentation

Another application of these models is Data Augmentation (DA): from sampling new latent codes  $z$  and decoding them, *fully synthetic multimodal* samples can be generated to augment a dataset. DA has been proven useful in many data-intensive deep learning applications (Chadebec et al., 2023). In a dedicated module `multivae.samplers`, we propose different ways of sampling latent codes  $z$  to further explore the generative abilities of these models.

## Statement of need

Although multimodal VAEs have interesting applications in different fields, the lack of easy-to-use and verified implementations might hinder applicative research. With MultiVae, we offer unified implementations, designed to be accessible even for non-specialists. In order to propose reliable implementations, we reproduced, whenever possible, a key result from the original paper. Some works similar to ours have grouped together model implementations: the [Multimodal VAE Comparison Toolkit](#) (Sejnova et al., 2024) includes 4 models and the [Pixyz](#) (Masahiro Suzuki & Matsuo, 2023) library contains 2 multimodal models. The work

68 closest to ours and released while we were developping our library is multi-view-ae ([Aguila](#)  
69 [et al., 2023](#)), which contains a dozen of models. We compare in a summarizing table below,  
70 the different features of each work. Our library complements what already exists: our API  
71 is quite different compared to previous work, the models implemented are not all the same,  
72 and for those we have in common, our implementation offers additional parameterization  
73 options. Indeed, for each model, we have made sure to offer great flexibility on parameters  
74 and to include all implementation details present in the original codes. Our library also offers  
75 additional features: **compatibility with incomplete data**, which we consider essential for real-life  
76 applications, and a range of tools dedicated to research and development of new algorithms:  
77 benchmark datasets, **metrics modules** and **samplers**, for testing and analyzing models.

## 78 List of models and features

79 In the Table below, we list available models and features, and compare to previous work. This  
80 symbol (✓\*) indicates that the implementation include additional options.

Models/ Features	Ours	( <a href="#">Aguila et al., 2023</a> )	( <a href="#">Sejnova et al., 2024</a> )
JMVAE ( <a href="#">Suzuki et al., 2016</a> )	✓*	✓	
MVAE( <a href="#">Wu &amp; Goodman, 2018</a> )	✓*	✓	✓

81 An important difference in our user-interface, is that we handle all training and model parameters  
82 within python dataclasses while ([Aguila et al., 2023](#); [Sejnova et al., 2024](#)) uses independant  
83 YAML configuration files.

## Code quality and documentation

Our code is available on Github (<https://github.com/AgatheSenellart/MultiVae>) and Pypi and we provide a full online documentation at (<https://multivae.readthedocs.io/>). The main features are illustrated through **tutorials** made available either as notebooks or scripts allowing users to get started easily. To further showcase how to use our library for research applications, we provide detailed case studies in the documentation.

## Acknowledgements

We are grateful to the authors of all the initial implementations of the models included in MultiVae.
